

Why successful digital transformation demands a

Zero trust security model

Digital transformation requires enterprise security and network evolution

Users, devices, applications and data are all moving outside the traditional enterprise perimeter.

40% of companies have more than 25% of their employees working remotely. ¹

67% of workers use their own devices at work. ²

50% of enterprises are running cloud-based apps nearly 50% of the time. ³

New business processes driven by digital transformation have increased the attack surface.

63% of all data breaches are the result of third parties. ⁴

390,000 new malicious programs are registered every day. ⁵

“Trust but Verify” is no longer an option as threats are moving inside the perimeter.

Greater than 40% of breaches originate with authorized users accessing unauthorized systems. ⁶

Ransomware attacks growing at a yearly rate of 350%. ⁷

In two years, ransomware damage costs has grown 15x. ⁸

Traditional perimeters are complex, increase risk, and are no longer conducive with today's business models.

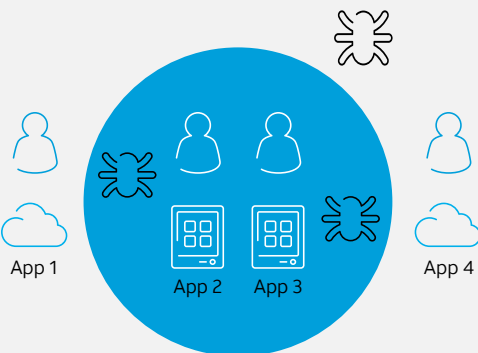

Expectation: Inside = trust

- Users and apps inside
- Trust but verify
- Full-network access

Reality: There is no inside...

- Users and apps anywhere
- Verify and never trust
- Application-level access

The number and types of devices on a corporate network are proliferating and the delineation between on-and off-network is no longer hard and fast.

Gartner predicts 20.4 billion+ devices will be installed by 2020. ⁹

77% of people own a mobile device. ¹⁰

It's time to adopt a cloud perimeter

Implement a zero trust security and delivery model for successful digital transformation.

How can AT&T Content Delivery Network help?

Our enterprise application access services help you facilitate secure remote access to business-critical enterprise and cloud applications and navigate today's untrustworthy and risky ecosystem.
